## About the Author

---

Jack A. Naglieri, Ph.D., is Research Professor at the Curry School of Education at the University of Virginia, Senior Research Scientist at the Devereux Center for Resilient Children, and Emeritus Professor of Psychology at George Mason University. He is a Fellow of APA Divisions 15 and 16, recipient of the 2001 Senior Scientist Award for APA Division 16 and the 2011 Italian American Psychology Assembly Award for Distinguished Contributions to Psychology, is a Diplomate in Assessment Psychology, earned a license as a School Psychologist in Virginia and Ohio, and earned School Psychology certifications in New York, Georgia, Arizona, and Ohio. Dr. Naglieri has focused his professional efforts on theoretical and psychometric issues concerning intelligence, cognitive interventions, diagnosis of learning and emotional disorders, and theoretical and measurement issues pertaining to protective factors related to resilience.

Dr. Naglieri is the author or coauthor of more than 250 scholarly papers, books, and tests. His scholarly research includes investigations related to exceptionalities such as mental impairment, specific learning disabilities, giftedness, and Attention Deficit Disorder; psychometric studies of tests such as the Wechsler Scales of Intelligence, Cognitive Assessment System, and the Kaufman Assessment Battery for Children; examination of race, gender, and ethnic differences in cognitive processing; fair assessment using nonverbal and neurocognitive processing tests; identification of gifted minorities, IDEA and identification of specific learning disabilities; and cognitively based mathematics interventions. He has authored various books, including *Essentials of CAS Assessment* (Naglieri, 1999), and coauthored books such as *Assessment of Cognitive Processes: The PASS Theory of Intelligence* (Das, Naglieri, & Kirby, 1994), *Helping Children Learn: Intervention Handouts for Use at School and Home, Second edition* (Naglieri & Pickering, 2010), *Essentials of Wechsler Nonverbal Assessment* (Brunnert, Naglieri, & Hardy-Braz, 2009), and *Helping All Gifted Children Learn: A Teacher's Guide to Using the NNAT2* (Naglieri, Brulles, & Lansdowne, 2009). Dr. Naglieri has also coedited books such as *Handbook of Assessment Psychology* (Graham & Naglieri, 2002), *Assessment of Autism Spectrum Disorders* (Goldstein, Naglieri, & Ozonoff, 2009), *Assessing Impairment: From Theory to Practice* (Goldstein & Naglieri, 2009), *A Practitioner's Guide to Assessment of Intelligence and Achievement* (Naglieri & Goldstein, 2009), and *Handbook of Executive Function* (Goldstein & Naglieri, 2013).

Dr. Naglieri's scholarly efforts also include development and publication of tests and rating scales. He began this work in the mid-1980s with the publication of the *Matrix Analogies Tests* (Naglieri, 1985), which became the *Naglieri Nonverbal Ability Test—Multilevel Form* (Naglieri, 1997), *Naglieri Nonverbal Ability Test—Second Edition* (2008) and now the *Naglieri Nonverbal Ability Test—Third Edition*

---

(2016). He also published the *Wechsler Nonverbal Scale of Ability* (Wechsler & Naglieri, 2008), the *Devereux Student Strength Assessment* (LeBuffe, Shapiro, & Naglieri, 2009), the *Autism Spectrum Rating Scale* (Goldstein & Naglieri, 2009), the *Comprehensive Executive Functioning Index* (Naglieri & Goldstein, 2013), and the *Cognitive Assessment System—Second Edition* (Naglieri, Das and Goldstein, 2014).

## CHAPTER 1

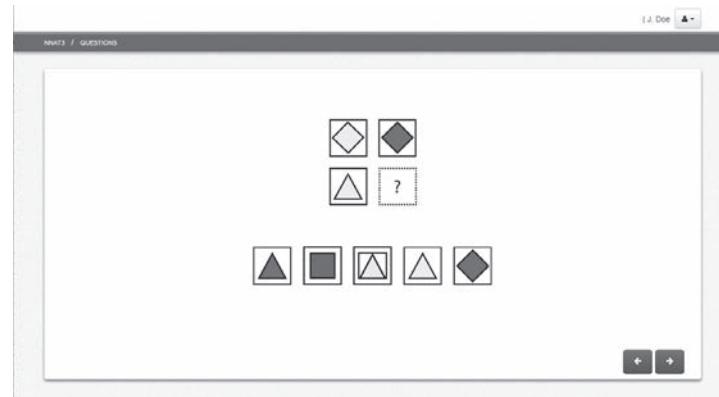

### PURPOSE AND DESIGN OF NNAT3 LEVELS A–D

The *Naglieri Nonverbal Ability Test*®—Third Edition (NNAT3 Levels A–D) is a brief, nonverbal measure of general ability that can be group administered in online or paper format in about 30 minutes to students aged 5 to 11.<sup>a</sup> For information about NNAT3 Levels E–G (grades 5–12), please see the NNAT3 Levels E–G Manual. The purpose of the NNAT3 is to measure general ability using abstract designs which are accessible to a wide variety of students including those with limited educational experiences, those who come from diverse cultural, socioeconomic, or linguistic backgrounds, and those who have language disabilities, autism spectrum disorder, or are deaf or hard of hearing. Because the NNAT3 items consist of geometric shapes that are universal and have no verbal content, and the directions are pictorial with minimal verbal instructions, NNAT3 has great utility as part of the process of identifying students for gifted/talented educational programs, especially for members of groups that have been underrepresented.

The NNAT3 is the latest in a series of related instruments spanning thirty years. It is a revision of the *Naglieri Nonverbal Ability Test*—Second Edition (NNAT2; Naglieri, 2007), which is based on the *Naglieri Nonverbal Ability Test—Multilevel Form* (NNAT-ML; Naglieri, 1997). The original instruments in this series were the *Matrix Analogies Test—Expanded Form* (MAT-EF; Naglieri, 1985a) and *Matrix Analogies Test—Short Form* (MAT-SF; Naglieri, 1985b).

The NNAT3 measures the student’s ability to look at a pattern that has a missing section, understand the relationships among the parts, and determine which of the five options correctly fills the gap. An example is shown in Figure 1.1. In this example, the student needs to comprehend the relationships between the two diamonds in the top row and the diamond and triangle in the left column. When the horizontal and vertical relationships are understood, then the answer (option 1) becomes clear.

Figure 1.1. Example of an NNAT3 Item

<sup>a</sup> Norms are also provided for children aged 4:0–4:11 so that NNAT3 Level A may be used with high-ability preschoolers. However, because of its difficulty, the test is not appropriate for general use with children younger than 5 years old.

The kind of thinking required to solve a question like this one, made up of shapes and colors, is essentially the same as the thinking required to solve a verbal question such as “Girl is to woman as boy is to . . . ?” In this case the relationships between girl and woman as well as girl and boy must be understood to arrive at the answer “man.” Although the thinking is the same whether one is reasoning with words or with shapes, one type requires knowledge of a particular language and, usually, the ability to read, whereas the other type does not require these skills.

The NNAT3 measures general ability—a widely used concept that has been studied since the early 1900s. Naglieri, Brülles, and Lansdowne (2009) described general ability as what allows people to solve a number of different kinds of problems that may involve words, pictures, sounds, or numbers. It may also require verbal, quantitative, or nonverbal reasoning; memory; sequencing; pattern recognition; insights; drawing inferences; and analyzing simple and complex ideas. In modern conceptions of ability, the particular type of thinking that NNAT3 questions require—that is, seeing relationships among components of the question and thinking of rules that can explain those relationships—is considered to be closely related to general ability (Carroll, 1993). Thus, it is not surprising that the various versions of NNAT have been found to be good predictors of academic achievement for students in diverse racial/ethnic groups or from diverse language backgrounds. The power of the concept of general ability makes this a useful approach for large-scale testing.

## Design

---

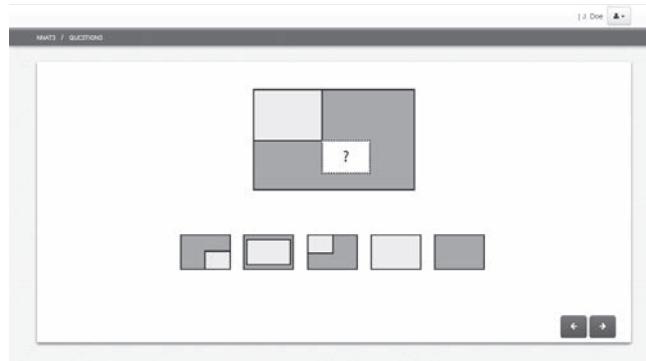

The NNAT3 consists of four levels (A, B, C, and D), each of which is designed specifically for students in the corresponding grade (i.e., K, 1, 2, and 3–4, respectively). Although kindergarten, Grade 1, and Grade 2 each have their own level, Level D is administered to students in Grades 3 and 4. Separate levels are provided for kindergarten through second grade because of the significant amount of development in ability that occurs during each of the early school years.

Unlike the previous versions of the test, the NNAT3 Levels A–D has two parallel forms (Form 1 and Form 2) at each level. The parallel forms are similar in the types of items they contain and in their level of difficulty, and they have no common items. This makes them useful in situations requiring repeated administrations, such as evaluating students’ progress over time or measuring the effectiveness of an intervention or program. Additionally, the lack of common items across forms helps to maintain item and test security.

Each form consists of 48 carefully selected items, arranged in approximate order of difficulty. The items were chosen based on content and level of difficulty. There are common items between adjacent levels within a form (for example, between Levels B and C of Form 1). The specifics of the item-selection and form-development processes are described in later sections of this manual.

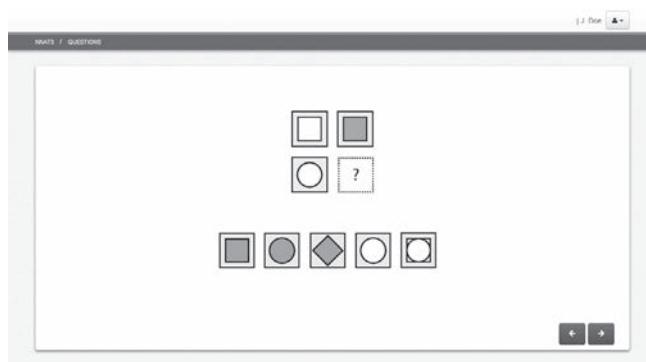

Although NNAT3 Levels A–D items are similar to NNAT2 items, they are all new. Test development was guided by the need to provide items of appropriate difficulty at every level and to vary the structure of the items. For example, the easiest items present a large rectangle with a piece missing (see an example in Figure 1.2). The child must choose the option that would complete the larger image, relying on an understanding of how the entire image is organized.

Figure 1.2. Example of an NNAT3 Item with Missing Piece

More difficult items show a set of images in a 2-by-2, 2-by-3, or 3-by-3 array. The elements of a relatively easy item form a simple pattern as shown in Figure 1.3. In this example, the student must recognize changes in shape and color across the horizontal and vertical dimensions to arrive at the correct answer. The items become more complex and difficult when there is an increase in the number of visual features and in the ways in which they can change (e.g., size, rotation, addition, or progression). This method of item development provided a full range of difficulty necessary to create norms which would measure ability nonverbally for a wide variety of individuals.

Figure 1.3. Example of an NNAT3 Item with Changes in Color and Shape

## Administration

The NNAT3 is designed to be administered to groups of students. At grades 2 and above, it can be given to entire classrooms, but smaller groups are recommended at kindergarten (up to five students) and Grade 1 (up to ten students). At any grade level, it is permissible to administer the NNAT3 to a single student.

The teacher reads the directions (in the language appropriate for the students) and leads the students through sample items, but once the actual test begins, the students work on their own. Students have 30 minutes to work on the test questions, and the overall administration, including directions, takes about 35 to 45 minutes.

The NNAT is considered a power test; that is, it is designed to measure the abilities of the test taker, regardless of his or her speed of performance. Power tests contain items with varying degrees of difficulty and allow enough time for test takers to attempt all items. Based on results from tryout and standardization, most students were able to complete the NNAT3 within 30 minutes. Additionally, a study comparing students who were given additional time to complete the NNAT2 versus those who were not found that students who got additional time did not obtain higher scores. As a result, the 30-minute administration time was deemed appropriate for the NNAT3.

Both the paper-and-pencil and computer-based versions of the NNAT3 are available at all levels. With paper administration at kindergarten and Grade 1, students mark their answers directly in a consumable, machine-scorable test booklet. At Grades 2–4, students may use either the consumable booklet or a reusable booklet with a separate machine-scorable answer sheet.

The choice of NNAT3 level to administer is based on the student’s grade, although the norms for the NNAT3 are based on age. The items at any given level span a wide range of difficulty so that the level is appropriate for students of different ages at that grade. If necessary, a student may be tested “out of level” (that is, using a level intended for a different grade), as long as the student’s age is within the range of valid ages shown in Table 1.1.

**Table 1.1. Grade and Valid Age Range for Each NNAT3 Level**

<b>Level</b>	<b>Grade(s)</b>	<b>Valid Age Range (year:month)</b>
A	Kindergarten	4:0 to 7:11
B	1	5:0 to 9:11
C	2	6:0 to 10:11
D	3–4	7:0 to 11:11

## Uses of NNAT3

---

The NNAT3 is well suited to evaluating general ability in a wide variety of children. It is a good predictor of academic achievement and is effective as part of the process of identifying gifted and talented students. In addition, the NNAT3 has several features that make it desirable for assessing diverse populations. The use of nonverbal test questions and pictorial directions enables valid and interpretable results to be obtained for students with varied linguistic or cultural backgrounds, such as English language learners. That is, the NNAT3 is particularly valuable for those who cannot be effectively and fairly assessed using tests with items that require knowledge and use of a particular language. These features are also beneficial for assessing students with developmental delays or challenges, the deaf and hard of hearing, students with autism spectrum disorder, and students with little or no schooling.

The NNAT3, therefore, has two primary uses. The first is to help in the identification of gifted and talented students, especially those from underrepresented groups; this use addresses one of the most serious challenges facing educators of gifted and talented students. The second use is to provide a measure of general ability for students of all ability levels for whom a language-free assessment is required.

---

## **CHAPTER 2**

### **INTERPRETATION AND APPLICATIONS**

NNAT3 results, like those from any test, should be interpreted in light of the student’s background, including classroom performance, social-emotional skills, motivation, and language skills. This chapter provides information designed to assist users in interpreting NNAT3 scores when making decisions about educational placement.

#### **Types of Scores**

---

The various types of scores provided for the NNAT3 have different uses and yield different kinds of information. Therefore, users should focus their interpretation on the particular score types that are most relevant to the purpose for which the test was administered. The score types are described in the following section. Please see the appendices at the end of this manual for score tables.

##### *Raw Scores*

The raw score is the number of items answered correctly. Raw scores are the basis for scaled scores (described below), but by themselves they provide little information about the level or quality of student performance. They can be interpreted only in reference to the number of items on the test.

##### *Scaled Scores*

The scaled-score system is based on a continuous scale of performance that spans across Levels A to D of the NNAT3. A higher scaled-score value indicates that the student was successful on more difficult items. A raw score on any NNAT3 level has a corresponding scaled-score value. A particular raw score will convert to a higher scaled score on a higher (more difficult) NNAT3 level than on a lower level.

Because the scaled-score system links all levels of the test together, it can be used to compare the performance of students taking different levels of the test. Once a raw score has been converted to its corresponding scaled score, the level that was administered is no longer relevant. This makes scaled scores especially suitable for comparing scores from different levels of the test, for studying growth in performance over time, and for testing out of level. The normative scores described below (NAI, percentile rank, stanine, and normal curve equivalent) are all based on the scaled score and the age of the examinee, rather than the raw score.

## *Normative Scores*

Normative scores describe how the student’s performance (scaled score) compares with the performance of other students of the same age in a nationally representative norm sample. For most purposes, normative scores are the most useful basis for interpretation. Because the NNAT3 is a measure of ability rather than academic achievement, the normative scores are based on age rather than grade.

### Naglieri Ability Index (NAI)

The Naglieri Ability Index (NAI) is a score on a scale that ranges from 40 to 160, with an average of 100 and a standard deviation of 16. An NAI of 100 represents the score that is the average for students of the same age. About 68% of students in the norm sample score within one standard deviation of 100 (that is, between NAIs of 84 and 116), and about 95% score within two standard deviations (68 to 132). Because NAIs are normalized standard scores, the relationship of NAIs to percentile ranks and stanines is the same for all ages and all NNAT3 levels.

### Percentile Rank

The percentile rank indicates the percentage of students of that age in the norm sample who scored at or below that scaled score. As noted above, there is a constant relationship between NAIs and percentile ranks. For example, an NAI of 116 converts to a percentile rank of 84, meaning that 84 percent of students in the norm sample earned NAIs of 116 or lower. An NAI of 100 corresponds to a percentile rank of 50, representing the average NAI for students in the norm sample.

Percentile ranks are valuable because they are easily interpreted and explained. However, they have certain disadvantages. One is that they are often confused with “percentage correct.” Another is that a given size difference between percentile ranks has different meaning at different score levels; for example, the difference in ability between percentile ranks of 90 and 95 is much greater than that between percentile ranks of 50 and 55. This characteristic results from the concentration of most scaled scores near the middle of the distribution, with relatively few scores at the extremes. Thus, although percentile ranks are very useful for describing the relative standing of a student within the reference group, they are less useful in describing differences between scores (such as between the scores of two students, or between a student’s scores at different times). Because they are not an equal-interval scale, percentile ranks cannot be averaged or used in arithmetical computations such as addition or subtraction.

## Stanine

The stanine scale is a simplified version of the NAI scale. Stanines range from 1 to 9 with an average of 5. The nine units of the stanine scale represent equal differences in ability; for example, the difference in ability between stanines 7 and 9 is the same as the difference in ability between stanines 1 and 3. Therefore, stanines may be averaged or used in other arithmetical computations.

In general, stanines 1, 2, and 3 are considered to reflect below-average performance; stanines 4, 5, and 6 reflect average performance; and stanines 7, 8, and 9 reflect above-average performance. Because stanine units are broader than those of the NAI and percentile rank scales, they possess somewhat greater stability and reduce the likelihood of misinterpretations of small differences in test scores.

## Normal Curve Equivalent

The normal curve equivalent (NCE) is another version of the NAI scale, this time with an average of 50 and a standard deviation of 21.06. Like NAIs and stanines, NCE scores can be used in arithmetical calculations such as averaging. The benefit of the NCE scale is that NCE scores of 1, 50, and 99 have percentile ranks of 1, 50, and 99, which may assist in interpretation.

All of the normative scores described in this section have fixed relationships with one another. Appendix C may be used to find the equivalent values on these different scales.

## *Guidelines for Interpreting Different Types of Scores*

Scores describe performance. A score should be selected for reporting based on its intended use. Stanine scores report performance on a very simple scale. Stanines range from a low of 1 to a high of 9, with 5 representing an average score. Percentile ranks are generally familiar to teachers and parents, are fairly easy to interpret, and offer more precision than stanines, allowing differentiation of 99 different points. The NAI score allows for even finer distinctions of differences in the performances of students at very high or very low levels. A percentile rank of 99, for example, corresponds to an NAI of 135 through 160. Percentile ranks cannot distinguish among students with NAIs of 135 or higher. In those instances in which a cut-score is used for identification, percentile ranks will usually be sufficient. For example, if a state or district uses a 95th-percentile rank to identify gifted and talented students, then using the percentile score for selection makes sense. But if it is necessary to distinguish students at the very high end of this scale, the NAI will allow for differentiation among students with percentile ranks at or above 99.

## Applications and Uses of NNAT3

The NNAT3 has a variety of educational applications. Like the NNAT2, it is a nonverbal measure of general ability that predicts scholastic achievement and is well suited to assessing groups of students with diverse backgrounds and characteristics.

The NNAT3 has ample ceiling for use in identifying gifted students, but it covers the full range of ability and therefore can also be useful in flagging students with low ability who may face difficulties in schoolwork. Furthermore, when used in conjunction with information about academic achievement, the NNAT3 can provide a broader picture of students who are struggling academically and identify students who may have learning problems, whose academic difficulties may be due to learning problems or limited English proficiency, or who may have had inadequate opportunity to learn. These groups of students are likely to do more poorly on tests that require verbal and quantitative knowledge than one that is nonverbal, making a test like the NNAT3 a good choice for accurate assessment.

The design of the NNAT3 items makes its use fair and appropriate with students who have hearing, language, or motor impairments, or who have impaired color vision.

For all of these reasons, the NNAT3 is particularly helpful when the goal is to find all gifted children, including those from diverse cultural, linguistic, or socioeconomic backgrounds, those who have had limited opportunity to learn, and those with hearing or motor impairments. These students may speak a different language or come from a different culture, but they have the potential to learn given the opportunity.

### *Using NNAT3 with Other Measures for Gifted/Talented Identification*

The NNAT3 can be used with other forms of assessment to help identify children who are gifted and talented and provide them with appropriate educational experiences. School districts often use a variety of measures (e.g., standardized achievement tests, creativity measures, grades, and in-class assignments) to identify students who should receive gifted and talented programming. This method of combining different types of information can affect the extent to which the broad reach of the NNAT3 is reflected in the results. Although the NNAT3 provides a way to measure ability that is particularly appropriate for children with limited English-language skills or those settings where enrichment in the home is limited, simply including the test in a larger group of measures will not automatically ensure that the process will identify children from a wide variety of backgrounds. To obtain the greatest benefit from inclusion of the NNAT3, the following factors should be considered.

1. If the identification process requires a series of tests, the NNAT3 should be administered first, and to all of the students. All students should be given the opportunity to demonstrate their abilities, not only those nominated for possible gifted/talented programs. For example, gifted students with limited English skills, learning problems, or inadequate learning opportunities will most likely not be identified if a verbal or quantitative test is administered first.

2. The manner in which information from different sources is combined makes a difference. For example, if students are required to obtain high scores on the NNAT3 and on a verbal or quantitative test, students whose academic achievement has been limited will tend to be excluded. Combining scores from very different tests can yield a misleading conclusion for students in diverse populations and mask a high score on the nonverbal measure of general ability.

The identification of gifted children who may not excel in academics despite high ability presents a challenge to teachers in gifted/talented education (see Winebrenner & Brulles, 2008). In such a situation, high scores on this nonverbal test of general ability allow us to identify those children who have great potential for academic attainment, and those students should be given the opportunity to get additional educational services (Naglieri, Brulles, & Lansdowne, 2009). Addressing the needs of these diverse populations can be accomplished with a variety of educational methods. Differentiated instruction, enrichment clusters, and part-time pull-out classes are common approaches; however, districts vary greatly in the gifted/talented services and programming they provide. Once a student has been found to have high general ability using the NNAT3, the instruction that is delivered must be tailored to the academic needs of the gifted child (Naglieri, Brulles, & Lansdowne, 2009). This will help students from a wide variety of cultural and linguistic groups receive the education they deserve.

## **What does the NNAT3 Measure?**

---

### *Concept of General Ability*

Group and individually administered intelligence tests that are popular today have been used in educational settings to measure *general ability* for 100 years. The origin of these tests was the Army Alpha and Army Beta tests devised by the U.S. Armed Forces in the early 1900s (Naglieri, 2015). These two tests differed on the basis of the content of the items. The Alpha battery included tests of general information (e.g., how many months are there in a year?), common sense (e.g., why do we use stoves?), verbal knowledge (synonyms/antonyms, verbal analogies), and quantitative skills like completing math word problems (e.g., how many are 40 plus 6 men?). Tests in the Beta battery were nonverbal and

included tasks such as completing a maze, constructing a design using blocks, remembering number-symbol associations, identifying what is missing in a picture, and copying geometric shapes. The Alpha test was viewed as an appropriate measure for literate men who could read and write English, while the Beta tests were intended for those with poor skills in written or spoken English (Yoakum & Yerkes, 1920). The testing procedures ensured that men “who fail in alpha are sent to beta in order that injustice by reason of relative unfamiliarity with English may be avoided” (Yoakum & Yerkes, 1920, p. 19). Thus, the Alpha and Beta tests were considered to be alternative methods of assessing general ability. These tests made a significant and long-lasting contribution to our understanding of how to measure and conceptualize general ability.

The initial thinking about the concept of general ability as a broad, general trait was described by Pintner (1923) when he wrote that “we did not start with a clear definition of general intelligence . . . [but] borrowed from every-day life a vague term implying all-round ability and . . . we [are] still attempting to define it more sharply and endow it with a stricter scientific connotation” (p. 53). Some years later Wechsler (1958) stated that even though his test of general ability was organized into verbal and performance scales, it did not measure two types of intelligence; rather, “the subtests are different measures of intelligence, not measures of different kinds of intelligence” (p. 64), and he viewed both types as equally valid (Boake, 2002). Similarly, the term “nonverbal” refers to the content of the test, not a type of ability (Naglieri, 2008). Thus, tests may differ in their content or specific demands but still measure the concept of general ability—what Spearman referred to as the “indifference of the indicator” (1927, p. 197).

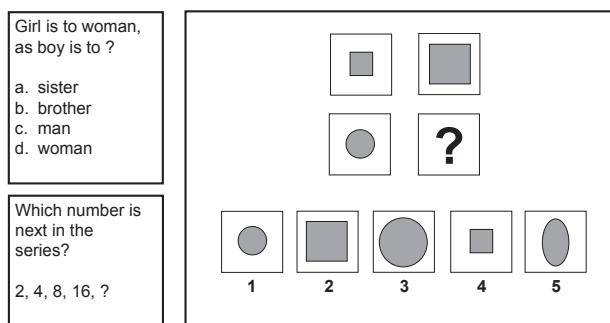

The diversity of tasks and content that may be utilized to measure general ability was highlighted by Naglieri, Brulles, and Lansdowne (2009, p. 5): “General ability is what allows people to solve a number of different kinds of problems that may involve words, pictures, sounds, or numbers. The test questions may also involve verbal, quantitative, or nonverbal reasoning, memory, sequencing, verbal and math skills, patterning, connecting ideas across and within content areas, insights, making connections, drawing inferences, and analyzing simple and complex ideas.”

There is considerable research support for the concept of general ability as measured by individually administered tests such as the Wechsler and Stanford-Binet (see Jensen, 1998, for a review) and by group tests such as the NNAT3. Among the most important sources of validity evidence for general ability tests is the fact that the scores the tests yield are good predictors of school achievement (Naglieri & Bornstein, 2003; Ramsey & Reynolds, 2004).

### *Verbal, Quantitative, and Nonverbal Ways of Measuring General Ability*

General ability can be measured using verbal, quantitative, or nonverbal test questions because of the similarity in the thinking required to answer these questions. In all three test types, the student must understand the relationships among the stimuli and must formulate and evaluate hypotheses about the rule that governs the pattern of relationships. Verbal tests (such as analogies) require the student to understand relationships among words and the concepts they represent, quantitative test questions require the student to understand relationships among numbers, and nonverbal test questions require the student to understand relationships among shapes. Examples of the three question types are shown in Figure 2.1.

Figure 2.1. Examples of Verbal, Quantitative, and Nonverbal Questions

Each of the questions illustrated in Figure 2.1 can only be solved if the examinee can understand the relationships among all the parts of the problem. The verbal analogy “Girl is to woman as boy is to \_\_\_\_?” requires that the examinee understand the way in which the words “girl” and “woman” are related and how “girl” and “boy” are related so that the answer (man) can be determined. Each of these pieces of information has meaning in relation to the others. The same is true for the quantitative reasoning item. In order to arrive at the answer, the student must infer the relationship between the first two numbers, 2 and 4 (the rule could be “add 2” or “multiply by 2”), then see if this relationship applies to the next pair of numbers, 4 and 8 (“add 2” does not work, but “multiply by 2” does), and then test the hypothesized rule by applying it to the last pair of numbers. These verbal and quantitative problems clearly require understanding of the relationships among the stimuli, which depends on knowledge (words and verbal concepts; numbers and arithmetic).

The nonverbal question also requires the student to understand the relationships among the shapes organized in the two-by-two matrix. To solve the problem, the relationships between the two shapes in the top row (change in size—little square becomes big square) and the two shapes in the left column (change in shape—little square becomes little circle) have to be understood and

applied to arrive at the answer (big circle). The relationships can be determined even if the shapes are not labeled as big and little or square and circle. Verbal and quantitative reasoning tests require both knowledge *and* thinking, whereas nonverbal reasoning tests require minimal knowledge but certainly demand thinking. Thus, general ability can be measured using verbal and quantitative tests that require knowledge *and* thinking, but nonverbal tests just require thinking.

---

## **CHAPTER 3**

### **CONTENT DEVELOPMENT, STANDARDIZATION, AND NORMS DEVELOPMENT**

This chapter describes how the content of NNAT3 Levels A–D was created, how it was evaluated and modified on the basis of item tryout, and how it was assembled into the standardization and final test forms. It also documents the standardization, including data-collection procedures, the demographic characteristics of the norm sample, and the method used to construct the norms.

#### **Item Creation**

---

The development process began with an initial pool of 480 new items which were organized into four levels based on estimated item difficulty. Graphical specifications for the new items were the same as for NNAT2 except for color. In order to ensure that NNAT3 items were appropriate for students with color blindness, careful attention was given to the selection of colors. NNAT3 items were constructed using the five colors of black, white, yellow, blue, and green, whereas NNAT2 items used a second shade of blue instead of green. The purpose of changing the color scheme was to make NNAT3 items more interesting and aesthetically pleasing. A team of color experts reviewed the colors and reported that students with color-vision deficits should be able to discriminate between the colors when they are adjacent, and match areas of the same color. Moreover, an examination of each item type revealed that the hues, saturation, and luminosity of each item were appropriate for individuals with different types of color blindness. Finally, the development team reviewed the items using software that simulates the effects of color blindness, and found that item content could be correctly perceived under each of the following color-blind conditions: monochromacy (complete), monochromacy (partial), protanopia or deutanopia (complete red-green), protanomaly or deutanomaly (partial red-green), tritanopia (complete blue-yellow), and tritanomaly (partial blue-yellow).

#### **Item Tryout**

---

The national tryout took place during May and June of 2014. Its primary purpose was to evaluate the difficulty, discrimination, and distractor functioning of a representative sample of the new items so that poorly functioning types of items could be revised or deleted and the new item types could be assigned to appropriate levels of the standardization forms. The items were created in pairs,

and only one item from each pair was included in the tryout. Also, the tryout included relatively few items that were highly similar to NNAT2 items, because these were expected to perform similarly to the NNAT2 originals. The reason for including these was to approximately link the difficulty scale of the NNAT3 tryout to the NNAT2 difficulty scale, thus allowing for a comparison of the difficulty of all NNAT3 items with NNAT2 items. It was assumed that the NNAT3 items that were based on NNAT2 items were, on average, as difficult as their NNAT2 counterparts. A total of 119 unique items were included in tryout, of which 42 were based on NNAT2 items.

### *Tryout Forms and Administration*

There was one 48-item tryout form at each of four levels: Level K (administered to preschool and kindergarten students), Level 1 (Grade 1), Level 2 (Grade 2), and Level 3 (Grades 3 and 4). Ten to fifteen items on each form were based on NNAT2 items. Additionally, to link performance across levels, each pair of adjacent levels had 12 items in common. For example, Level 2 shared 12 items with Level 1 and 12 items with Level 3.

All tryout forms were administered on computer using a mouse. Pre-K students were tested in a one-on-one setting with their teachers who recorded the responses. Kindergarten and first-grade students took the assessment in small groups of up to five or ten students, respectively, and recorded their own responses. Second-, third-, and fourth-grade students took the tryout in classroom-size groups and recorded their own responses. Students responded by using a computer mouse to click on their answer choices. Any student who had difficulty manipulating the mouse was assisted by the teacher or proctor.

Administration procedures resembled those for NNAT2. The same kinds of sample items were used, and there was a 30-minute time limit (after the samples). Students were able to skip items and could go back to review earlier items.

### *Tryout Sample*

Data was collected at eight sites in urban, suburban, and rural areas of the southern and midwestern United States. A total of 1,074 public- and private-school students in Pre-K through Grade 4 participated. The sample was designed to reflect a wide range of abilities. Because the tryout was conducted at the end of the school year, children attending preschool were included to provide an approximation of how kindergarten children would perform at the beginning of the school year. Participating schools received monetary compensation.

Table 3.1 shows the representation of the tryout sample by gender and ethnicity. Approximately 67% of the students at kindergarten through Grade 4 were in a free or reduced-price lunch program, and 5% of the overall sample were English language learners.

**Table 3.1. Distribution of Gender and Ethnicity in the Tryout Sample**

Characteristic	N	Percentage
All	1,074	
Female	476	44
Male	598	56
African American	39	4
Asian	17	2
Hispanic	156	15
White	830	77
Other	32	3

### *Tryout Results*

Classical item-analysis procedures were applied separately at each grade level, and a single Rasch (IRT) calibration was performed on the entire sample. The classical statistics included difficulty ( $p$ , or proportion passing), discrimination (the correlation of item score with total score), and distractor information (proportion choosing each distractor, and correlation of each distractor with total score). Grade-level  $p$  values were especially useful for identifying the most appropriate level for each item. Because item-total correlations are affected by difficulty, items were flagged for scrutiny if their item-total correlation was low in comparison to other items of similar difficulty. All distractors were evaluated to detect any instances where a distractor attracted high-ability examinees, and distractor information was invaluable in diagnosing items with poor discrimination.

The Rasch item analysis yielded a difficulty value on the logit scale that spanned across all forms and levels, and an index of discrimination (infit mean square) that described how well the item differentiated between lower-ability and higher-ability examinees. Rasch logit difficulties were invaluable for comparing items across levels and for controlling the difficulty of standardization forms. The discrimination index is a robust flag for poor item functioning because it is largely independent of difficulty and it summarizes the information from all the levels at which an item was administered.

Tryout items that were highly similar to NNAT2 items were used to roughly align the Rasch difficulty scale in the tryout with the corresponding scale for NNAT2. Tryout logit difficulties for these 42 NNAT3 items were plotted against the logit difficulties of the corresponding NNAT2 items, and a few outliers were identified and removed. For the remaining items, tryout and NNAT2 difficulties correlated 0.84. The mean difference between the two sets of difficulty values was used as the equating constant between the tryout and NNAT2 scales. Adding this constant to a tryout difficulty value gave an estimate of the item's difficulty on the NNAT2 scale, allowing some control over the difficulty of NNAT3 standardization forms relative to NNAT2 forms.

About 7% of the 119 tryout items were removed from the item pool because of poor discrimination that did not appear to be remediable through revision. Another 9% of items were dropped because they were either too easy or too difficult for the level at which they had been administered, and so the tryout did not provide useful information about their functioning. The remaining items were retained, either in their tryout versions or with modifications that were indicated by the item analyses; often, modifications involved revision or replacement of distractors.

## **Standardization**

Standardization was conducted during the 2014–2015 school year, with most norm cases collected during the fall. In addition to norming, standardization included an alternate-form reliability study, validity studies with NNAT2 and the *Otis-Lennon School Ability Test*®, Eighth Edition (OLSAT 8), and a study to compare online and paper administration modes. Except for this last study, all standardization administrations were on computer using a mouse.

There were two 48-item forms (Forms 1 and 2) at each of four levels: Level A (kindergarten), Level B (Grade 1), Level C (Grade 2), and Level D (Grades 3 and 4). At each level, these two forms were parallel in content and difficulty and had virtually no common items. In addition, a 48-item equating form was created at each level that contained items from Forms 1 and 2 as well as unique item pairs that could serve as replacements, if necessary.

### *Assembly of Standardization Forms*

Forms 1 and 2 of each level were designed to resemble the corresponding NNAT2 form in content and difficulty. Regarding content, items were chosen so that these forms would have a similar distribution of broad item types as the NNAT2 form at that level. The forms were also designed to have a similar

distribution of item difficulties (on the NNAT2 scale), although with a few more items at the highest difficulty level. The target difficulty ranges and the mean difficulties of the forms for each level are presented in Table 3.2.

**Table 3.2. Difficulty of Items on NNAT3 Standardization Forms 1 and 2**

Level	Target Difficulty Range	Mean Difficulty of Forms
A	-4.5 to 1.5	-1.6
B	-4.0 to 2.0	-1.0
C	-3.9 to 2.5	-0.7
D	-3.9 to 3.5	0.0

*Note.* Values are Rasch logits (on the NNAT2 scale). Lower numbers indicate easier items, and higher numbers represent more difficult items.

The first step in forms construction was to build the Level A forms. Items were selected according to three criteria: content (a target distribution of item types), difficulty (a target distribution of Rasch logit values), and discrimination (item-total correlation and mean square infit). In addition, an effort was made to maximize the diversity of item appearance on each form. While selecting items, those with poor discrimination in tryout were excluded from the forms in order to enhance reliability.

Items were selected in pairs so that one of each pair was included on Form 1 and the other on Form 2. Paired items were very similar, but not so similar that the only difference between them was a change in color or a minor change in the shape of elements.

Next, 15 items were selected from Level A Form 1 for use in Level B Form 1 to provide vertical (across-level) linking, and the same was done for Form 2. The linking items reflected the distribution of content and the entire range of difficulty of the Level A forms. Thirty-three unique items were then added to each Level B form according to the desired distributions of item types and difficulty. These 33 items were also chosen in pairs (66 items total), with one of each pair included on Form 1 and the other on Form 2. This process was repeated to create Level C forms linked to Level B, and Level D forms linked to Level C.

Each of the parallel forms at a level shared fifteen items with the corresponding form at the level(s) immediately above and below it. However, no individual item spanned more than three levels. Also, with one exception there were no common items between Form 1 and Form 2; the exception was an item that appeared on

Level C Form 1 and Level D Form 2. The forms were designed in this manner to allow for linking across the levels via a vertical scaling process, while allowing users to minimize item exposure through their choice of form.

The equating form at each level was developed to provide a linkage between Forms 1 and 2 and to provide replacement pairs of items should they be needed. Fifteen items from Form 1 and fifteen items from Form 2 were selected for the equating form. These items reflected the range of difficulty and item type distribution of Forms 1 and 2 for that level. The items selected from Forms 1 and 2 were not from the same pairs, in order to avoid presenting two highly similar items to the student. Thus, the linking items selected for the equating form made up a miniature version of Forms 1 and 2. For each level, the remaining 18 items consisted of nine new pairs that could be substituted on Forms 1 and 2 in the event that an item pair on those forms did not perform as expected during the standardization process.

## **Test Administration**

The standardization forms were administered during the 2014–2015 school year at 113 schools around the country. All administrations were on computer using a mouse, except for those in the online-paper comparison study. In order to provide norms down to age 4 years 0 months, a specially designed pair of Pre-K forms were administered individually, as had been done in tryout. Levels A and B were administered in small groups (up to 5 or 10 students, respectively).

## **NORMS DEVELOPMENT**

### **Norm Sample**

The NNAT3 norm sample was drawn from 113 schools and preschools in 27 states. Schools were chosen to be representative of the national school population with respect to ethnicity, socioeconomic status, geographical region, urbanicity, and type of school (public or private). Socioeconomic status was measured at the school level by the percentage of students receiving free or reduced-price lunches, grouped into five levels that each correspond to about one-fifth of schools in the United States. For preschools, the socioeconomic status (SES) of the local public schools was used. A list of the participating schools and preschools can be found in Appendix D.

Although schools were selected according to the demographic criteria described above, statistical weighting was applied after testing in order to improve the match of the norm sample to the national population. The weighting procedure involved random deletion or duplication of cases until the desired sample characteristics were obtained. Table 3.3 shows the number of actual cases in the norm sample at each year of age followed by the *N* counts after weighting. Table 3.4 presents the demographic characteristics of the weighted norm sample.

**Table 3.3. Numbers of Cases by Age in the NNAT3 Norm Sample**

Age	<i>N</i>	
	Actual	Adjusted
4	645	785
5	2,366	1,980
6	1,459	1,494
7	1,384	1,488
8	1,795	1,785
9	879	961
10	785	764
11	642	665
Total	10,225	9,992

**Table 3.4. Demographic Characteristics of the NNAT3 Norm Sample**

		Percentage of Total U.S. School Enrollment Ages 4:0 to 11:0	Percentage of Students in Norm Sample
<b>Gender</b>	Female	48.9	48.2
	Male	51.1	51.8
<b>Ethnicity</b>	African American	13.7	14.2
	Asian	4.8	4.8
	Hispanic	24.3	23.9
	White	51.8	52.0
	Other	5.5	5.2
<b>SES</b>	Low	21.7	19.1
	Low-Middle	20.1	21.8
	Middle	18.5	20.2
	High-Middle	19.2	19.3
	High	20.5	19.6
<b>Geographic Region</b>	Northeast	16.4	17.7
	Midwest	21.5	23.6
	South	38.0	38.1
	West	24.1	20.6
<b>Urbanicity</b>	Urban	21.7	24.1
	Suburban	47.3	42.2
	Rural	31.0	33.7
<b>School Type</b>	Public	85.7	85.6
	Private/Catholic	14.3	14.4

## Norms Construction

The NNAT3 age norms are based on scaled scores rather than on raw scores. The scaled score system for the NNAT3 links Levels A through D of the test together, yielding a continuous scale that makes it possible to compare the performance of students taking different forms. Once a raw score is converted to its corresponding scaled score, the level and form that was administered is no longer relevant, because the NAI, percentile rank, stanine, and normal curve equivalent (NCE) are all based on the scaled score and the age of the examinee rather than the raw score.

NNAT3 scaled scores are a linear transformation of Rasch ability scores from a single joint calibration of all standardization forms across levels. As noted earlier in this chapter, Forms 1 and 2 at each level are linked through a common-item equating (using the equating form), and levels are vertically linked through common items at adjacent levels. The linear transformation was constructed so that the scaled scores would have a similar range as for the corresponding levels of NNAT2. However, a constant of 1,000 was added to the NNAT3 scaled scores to differentiate them from NNAT2 scaled scores, to prevent accidental misinterpretation. Thus, NNAT3 scaled scores for Levels A to D have a range of approximately 1,300 to 1,800.

The percentile-smoothing method was used to construct the age-norm tables that convert scaled scores to NAI scores. In the initial phase, the data was smoothed vertically (that is, within age). To do this, mid-interval percentile values for the scaled-score distribution at each year of age were calculated for key percentiles (every tenth percentile from 10 through 90, plus 1, 5, 95, and 99). These percentiles were converted to the NAI scale ( $M = 100$ ,  $SD = 16$ ) using a normal-curve area transformation. Scaled scores were plotted against these preliminary NAI scores, and the resulting trend was smoothed by fitting a simple curve (typically linear or quadratic). From this curve, scaled scores corresponding to every fourth NAI value from 64 to 136 were obtained.

The second phase was to fit a growth curve to the trend of scaled scores corresponding to each NAI value across age. For example, a curve was fitted to the trend of scaled scores corresponding to an NAI of 100 (50th percentile) across the range from age 4 to age 11. This was accomplished using CurveExpert Pro (Hyams, 2014), a software program that identifies the best-fitting curves from a large number of curve types. By reviewing the best curve types at different NAI levels, it was possible to select one curve type that had consistently good fit and yielded curves at adjacent NAI values that had similar shape and did not overlap.

Next, for each three-month age range, the scaled-score values for the various NAI levels were read from the growth curves and plotted against NAI. Simple polynomial curves were fitted to these within-age plots, yielding smoothed scaled-score-to-NAI conversions. These curves also provided extrapolation to NAI values of 40 and 160. The final step was to interpolate between adjacent curves in order to obtain norms for each month from 4:0 (4 years 0 months) through 9:11. One-month age intervals are used at these younger ages where growth in performance is relatively rapid so that the NAI for a given scaled score usually will differ by only one point between adjacent age groups.

When the final norm table was applied to the full standardization sample, the mean was 100.2 and the standard deviation was 15.8.

## DEVELOPMENT OF FINAL FORMS

The published version of NNAT3 has two parallel, non-overlapping, 48-item forms at each of four levels (A through D). These are nearly the same as standardization Forms 1 and 2, but in order to achieve the desired level of difficulty and to maximize reliability, a few items were dropped from the standardization forms and replaced with more appropriate items that performed well in standardization. Items were dropped if they had relatively poor discrimination (item-total correlation and infit) or if their difficulty or the behavior of the distractors pointed to an aspect of item content that was ambiguous or confusing. In addition, Levels A, B, and C needed some additional greater-difficulty items in order to meet the design requirements, and so a few easy items were replaced with more challenging ones. On average, four items were replaced per form.

Replacement items usually came (in pairs) from the equating form of the same level. However, in situations in which form difficulty was the issue, it was sometimes necessary to obtain replacement items from the next-higher level of the equating form. Table 3.5 shows the number and source of replacement items on each standardization form.

**Table 3.5. Number and Source of Replacement Items on NNAT3 Final Forms**

Level	Form	Replacement Items	
		From Same Level	From Higher Level
A	1	1	2
	2	2	0
B	1	2	1
	2	3	0
C	1	4	2
	2	3	1
D	1	5	0
	2	7	0

These item replacements sometimes involved vertical linking items (i.e., items that were common between adjacent levels of the standardization forms). As a result, each final NNAT3 form has between 14 and 17 items in common with the corresponding form at the levels immediately above and below it.

After making the item replacements, the difficulty of the final forms was compared to the difficulty of the NNAT3 standardization forms and the NNAT2. The final NNAT3 forms meet the aforementioned desired target difficulties and are of appropriate difficulty for the intended grade levels.

---

## CHAPTER 4

### EVIDENCE OF RELIABILITY AND VALIDITY

#### RELIABILITY

Test-score reliability refers to the consistency of examinees' scores when they are tested on different occasions close together in time, or using different (although parallel) forms. It indicates the precision of test scores, that is, their freedom from the effects of measurement error. Reliability can be assessed in many ways. Therefore, it is important to determine the most appropriate types of reliability for a particular assessment.

#### IRT-Based Reliability

One approach to reliability estimation uses the Rasch item response theory model to calculate, for each level of examinee ability, the standard error of measurement (*SEM*) of the examinee's ability score when taking a set of items with known difficulties. The average *SEM* in the sample of examinees can then be compared to the standard deviation of ability scores in the sample to compute reliability, using the fundamental formula (Crocker & Algina, 1986):

$$\text{Reliability} = 1 - (\text{SEM}^2)/(\text{SD}^2)$$

The *SEM* in this formula is the square root of the mean of the squared *SEMs* in the sample.

Green, Bock, Humphreys, Linn, and Reckase (1984) introduced this method under the name *marginal reliability*. IRT-based (or marginal) reliabilities agree closely with internal-consistency reliability measures such as coefficient alpha and split-half reliability (Dimitrov, 2003; Wainer & Thissen, 1996). They estimate the consistency of scores that would be obtained on different but parallel sets of items.

Table 4.1 reports IRT-based reliabilities for NNAT3 by level and form (and, for Level D, by grade). The sample at each level is the full weighted set of examinees in the norm sample who took that level, including those who took the equating form. The mean and standard deviation of Rasch ability scores reflect the entire sample at that level. Likewise, the mean *SEM* for each form (in Rasch ability score units) is based on the *SEM* for each student in the norm sample, calculated by comparing their ability score with the difficulties of the items on that form.

**Table 4.1. IRT-Based Reliabilities by Level and Form**

Level	N	Ability Scores		Form 1		Form 2	
		Mean	SD	Mean SEM	Reliability	Mean SEM	Reliability
A	1,856	−2.13	1.16	.40	.88	.38	.88
B	1,687	−0.58	1.13	.39	.88	.39	.88
C	1,922	−0.21	0.94	.37	.84	.38	.84
D (Gr 3)	1,103	0.26	0.84	.38	.80	.37	.80
D (Gr 4)	1,021	0.73	0.93	.38	.83	.38	.83
Mean					.85		.85

Note: Mean SEM is the average SEM of student-ability scores. Mean reliabilities were calculated using Fisher's z transformation.

## Alternate-Form Reliability

When parallel forms of a test are available, an alternate-form study is a good way of estimating the consistency of scores obtained on different occasions using different items. The time interval between administrations should be brief enough so that it can be assumed that student-ability levels have not changed, but long enough to allow for variations in mood, alertness, and other factors that could affect performance. Two such alternate-form reliability studies were conducted during NNAT3 standardization. In the first study, both forms were administered online. In the second study, one form was administered online and the other was administered using paper.

### *Online Study*

All 524 participants took both forms of the NNAT3 online. Within one to four weeks after standardization testing (mean interval = 18 days), some students who had taken Form 1 were given Form 2, and an approximately equal number of students who had taken Form 2 were given Form 1. (Only the initial administrations were used for norming.) In order to remove the influence of the order effect, correlations were calculated separately for each sequence group and then averaged. The results (shown in Table 4.2) indicate that scores on the alternate forms were highly correlated, with an average correlation of 0.79.

**Table 4.2. Alternate-Form Reliability (Online), by Level**

Level	Sequence	N	Form 1		Form 2		r	Adjusted r	Order Effect
			Mean	SD	Mean	SD			
A	Form 1–Form2	24	91.2	16.3	96.6	15.5	.72	.71	5.0
	Form 2–Form 1	21	102.3	19.3	97.7	16.2	.87	.86	
		45					<b>Mean r</b>	<b>.80</b>	
B	Form 1–Form2	63	101.0	14.7	105.3	16.6	.67	.70	4.2
	Form 2–Form 1	87	102.1	14.8	98.0	16.0	.69	.69	
		150					<b>Mean r</b>	<b>.70</b>	
C	Form 1–Form2	89	96.5	16.4	99.3	14.8	.81	.80	2.9
	Form 2–Form 1	112	99.6	15.6	96.7	13.7	.78	.83	
		201					<b>Mean r</b>	<b>.82</b>	
D	Form 1–Form2	62	100.9	13.9	101.4	16.6	.79	.83	3.0
	Form 2–Form 1	66	104.0	13.1	98.6	13.5	.76	.81	
		128					<b>Mean r</b>	<b>.82</b>	
								<b>Average</b>	<b>.79</b>
									3.8

Note. Mean correlations were calculated using Fisher's *z* transformation. Correlations were adjusted for range restriction on the first administration (Cohen, Cohen, West, & Aiken, 2003).

The order effect (sometimes referred to as the practice effect) is the average increase in scores between the first and second administrations. In this study, the order effect averages about four NAI points. This effect is similar in size to the order effects found in the NNAT3–NNAT2 correlation study and the study comparing online and paper administration, both of which are described below. Users of NNAT3 should be aware that when different NNAT forms are administered twice within a period of weeks or a few months, scores on the second administration are likely to be several points higher because of prior experience with these types of items.

### *Online-Paper Study*

The primary purpose of this study was to evaluate the comparability of scores from online- and paper- administration formats, and the results relevant to that evaluation are discussed later in this chapter. However, the study also provides evidence of the consistency of scores obtained on alternate forms administered using different modes.

At each NNAT3 level, about 480 students took Form 1 first and Form 2 one to four weeks later. About half of the students took online administration first and paper second, and the others took paper administration first and online second. NAI scores were computed using the raw-score-to-scaled-score conversion table appropriate for each administration mode. Table 4.3 presents NAI means and intercorrelations separately for each sequence group, and the average correlation across sequence groups. Alternate-form/alternate-mode correlations average 0.79, the same as in the online study. Also, the order effect (4.0) is similar to that in the previous study (3.8).

**Table 4.3. Alternate-Form Reliability (Online–Paper), by Level**

Level	Sequence	<i>N</i>	Paper		Online		<i>r</i>	Adjusted <i>r</i>	Order Effect
			Mean	<i>SD</i>	Mean	<i>SD</i>			
A	Paper–Online	219	96.1	15.5	101.2	15.4	.83	.84	4.9
	Online–Paper	267	98.1	15.6	93.3	15.6	.75	.75	
		486					<b>Mean <i>r</i></b>	<b>.80</b>	
B	Paper–Online	257	104.8	15.3	112.1	15.3	.79	.80	6.8
	Online–Paper	224	111.6	14.5	105.3	15.4	.71	.72	
		481					<b>Mean <i>r</i></b>	<b>.77</b>

## VALIDITY

The validity of test scores is the accuracy of inferences based on them. Inferences can be about a characteristic of the person, the likelihood of the person succeeding in a particular educational program, and so on. Often, validity is assessed by examining the relationship between test scores on the instrument of interest and scores on other instruments believed to measure the same or a similar construct.

In order to assess the validity of the NNAT3, studies were conducted during standardization of its relationship with two other measures of cognitive ability: NNAT2 and the *Otis-Lennon School Ability Test*, eighth edition (OLSAT 8). Correlating performance on the NNAT3 with scores on other ability tests provides important insight into what the test measures and whether it performs as expected in relation to other variables.

### Correlation with NNAT2

---

Although NNAT3 consists of an entirely new set of items, the item types are the same as on NNAT2, and each level of the NNAT3 and NNAT2 forms have a similar representation of types. Therefore, NNAT3 and NNAT2 are expected to measure the same construct and to correlate highly with each other.

In this study, both tests were administered online, within one to four weeks of each other. Most of the 368 students (92%) took Form 2 of NNAT3. Some of the participants took NNAT3 first, as part of the norming study, and the others took NNAT2 first. Although there were more students in the NNAT3-first condition, this did not affect the results because correlations were computed separately for each sequence group and then averaged. Results for Level D are included because they provide valid information about the NNAT3–NNAT2 correlation, even though only cases with NNAT3 given first were available.

Table 4.4 shows the means and standard deviations of NAI scores on NNAT3 and NNAT2, and the correlations between them, by level. NAI scores on the two tests correlate highly (in the high 0.70s), indicating that they measure the same construct. Scores on the second administration average 3.5 points higher than on the first administration, very close in size to the order effect found in the alternate-form studies reported earlier in this chapter. Also, average NAI scores are approximately 2.5 points higher on NNAT3 than NNAT2.

**Table 4.4. Correlations between NNAT3 and NNAT2 NAI Scores**

Level	N	NNAT2 First				r	NNAT3 First				Average Correlation <sup>a</sup>		
		NNAT2		NNAT3			N	Mean	SD	Mean	SD		
		Mean	SD	Mean	SD								
A	58	104.7	13.8	109.0	12.6	.68	56	99.1	14.6	92.6	11.3	.74	.79

Weighted mean of within-level r:													.78

<sup>a</sup>Weighted mean of adjusted correlations

Note. Mean correlations were calculated using Fisher's z transformation. Correlations were adjusted for range restriction on the first administration (Cohen, Cohen, West, & Aiken, 2003).

### ***Correlation with Otis-Lennon School Ability Test, Eighth Edition (OLSAT 8)***

OLSAT 8 is an ability test that includes verbal as well as nonverbal items, and uses verbal instructions in contrast to the pictorial directions of NNAT3. A comparison of these two tests provides important information about NNAT3 validity because both tests attempt to measure general ability.

A group of 366 students who took NNAT3 online as part of the norming study also took OLSAT 8 (administered in paper-and-pencil format) within four weeks after taking NNAT3. Administration sequence was not counterbalanced because the study was not intended to compare score levels on the two instruments. Table 4.5 shows the means and standard deviations of NNAT3 NAI scores and OLSAT 8 School Ability Index (SAI) scores, and the correlations between them. The NAI scores correlated higher with the OLSAT 8 Nonverbal and Total scores than with the OLSAT 8 Verbal score. In general, the results suggest that the two assessments measure a similar construct.

**Table 4.5. Correlations between NNAT3 and OLSAT 8 Scores**

NNAT3		OLSAT 8 SAI			NNAT3 NAI		Correlation	
Level	N	Scale	M	SD	M	SD	r	Adj r
A	98	Total	112.7	15.0	114.0	23.4	.55	.41
	98	Verbal	109.7	15.2			.25	.17
	98	Nonverbal	113.5	17.0			.66	.51
B	86	Total	100.5	15.3	102.2	16.1	.55	.54
	86	Verbal	101.2	15.2			.43	.43
	86	Nonverbal	99.0	15.2			.55	.55
C	77	Total	103.4	14.0	104.5	13.8	.56	.62
	77	Verbal	107.4	16.1			.49	.55
	77	Nonverbal	99.2	11.9			.56	.61
D	105	Total	92.5	14.0	98.7	15.7	.58	.59
	105	Verbal	91.8	14.9			.48	.49
	105	Nonverbal	93.8	15.1			.57	.58

Note. Correlations were adjusted for range restriction on NNAT3 (Cohen, Cohen, West, & Aiken, 2003).

## OTHER STUDIES

### Comparison of Online and Paper Administration

The main purpose of this study was to see if the administration mode (online or paper) has an effect on NNAT3 scores, and if so, to make appropriate adjustments in the scoring procedures so that scores from both modes are comparable. A secondary purpose was to obtain additional information about alternate-form reliability; those results were reported earlier in this chapter.

At each NNAT3 level, a sample of between 482 and 490 students participated in the study. All students took Form 1 first and form 2 second, with an interval of 1 to 4 weeks. Scaled scores based on online administration were used throughout the analysis because at the time this study was conducted, NAI norms had not yet been constructed. The order of administration modes was approximately counterbalanced, and scores from the online-first administrations were included in the NNAT3 norming sample.

Multiple regression was used to evaluate whether there was a mode effect. The Time 2 scaled score was predicted by the Time 1 scaled score, a dummy variable representing administration sequence (online-paper or paper-online),

and the product of these two variables representing the interaction of mode and ability. A significant interaction term meant that the mode effect was different at different score levels. If there was no significant interaction, then the analysis was rerun without the interaction term, and a significant sequence term would indicate the existence of a mode effect (i.e., the level of the Time 2 score relative to the Time 1 score differed according to whether the Time 2 administration was online or paper).

At each NNAT3 level there was no significant interaction (at  $p < .05$ ), and there was a significant mode effect (at  $p < .01$ ) with higher scaled scores on the paper administration. Because the absence of interaction meant that the mode effect was uniform (that is, consistent across score levels), a simple mean-difference equating was appropriate. A small number of cases were deleted at random to equalize the number of students taking online first or paper first, and then the overall mean scores for online and paper administration were calculated and compared, as shown in Table 4.6. When converted to NAI points, the difference (which represents the mode effect) ranged from 2.2 to 3.1.

**Table 4.6. Comparison of NNAT3 Scaled Scores from Paper and Online Administrations**

<b>Level</b>	<b>N</b>	<b>Paper</b>		<b>Online</b>		<b>Difference (mode effect)</b>	
		<b>Mean</b>	<b>SD</b>	<b>Mean</b>	<b>SD</b>	<b>Scaled Scores</b>	<b>NAI</b>
A	444	1,551.8	38.7	1,544.3	40.3	7.4	3.1
B	448	1,602.7	35.8	1,596.8	35.8	5.9	2.5
C	468	1,614.7	31.4	1,609.9	33.0	4.9	2.1
D	476	1,631.0	37.6	1,626.2	34.2	5.8	2.2

The mode effect has been incorporated into the raw-score-to-scaled-score conversion tables so that students of the same ability have the same expected scaled score and NAI regardless of whether they take NNAT3 through an online or a paper administration.

## CHAPTER 5

# NNAT3 LOWER LEVELS 2018 NORMS UPDATE

The NNAT3 Lower Level norms were updated in 2018 to provide national norms based on an expanded representative norm sample, and to extend the upper end of the norms age range from 11 years 5 months to 11 years 11 months. There were no changes in the test items or forms, the method of administration or scoring, or the scaled scores. The only change was in the age-norm tables (Appendix B) used to convert scaled scores to Naglieri Ability Index (NAI) scores.

The updated norms were based on a nationally representative sample of 85,959 students, ages 4 years 0 months to 11 years 11 months. The sample came from two sources. Most students were drawn from those who took NNAT3 in 2016–2017, whose tests were scored by Pearson (either through online administration or central scoring of paper administrations), and whose schools used the test for universal screening at a grade level and were eligible for participation (i.e., did not prohibit their data from being used). Grade 5 students within the target age range were included so that the sample fully represented the population of 11-year-olds, and their Level E scaled scores were converted to equivalent Lower Levels scaled scores. The remainder of the sample consisted of students in the original NNAT3 norm sample (described in Chapter 3) who took the test online as part of the 2014–2015 standardization.

### **Sampling Procedures**

---

A combination of stratified random sampling and statistical weighting was used to achieve a close match of the normative update sample to the national student population demographic characteristics, as reported in the 2015 Census Data from the National Center for Educational Statistics, United States Department of Education. The demographic characteristics controlled were race/ethnicity, socioeconomic status (SES—percentage of students receiving free/reduced lunch), geographic region, urbanicity, and school type (public or private). All demographic variables were controlled at the school level. The weighting procedure involved random deletion or duplication of cases to achieve alignment to the target distributions of demographic variables at each year of age.

Table 5.1 displays the demographic characteristics of the NNAT3 2018 normative update sample. Characteristics of this sample were very consistent with the 2015 census in terms of geographic region, SES, urbanicity, ethnicity, type of school, and gender.

**Table 5.1. Demographic Characteristics of the NNAT3 2018 Updated Normative Sample**

<b>N = 85,959</b>		<b>Percentage of Total U.S. School Enrollment<sup>1</sup></b>	<b>Percentage of Students in 2017 Norms Update Sample</b>
<b>Ethnicity</b>	African American	13.8	15.0
	Asian	4.8	5.5
	Hispanic	25.1	25.6
	White	50.5	49.2
	Other	5.8	4.7
<b>SES</b>	Low	20.9	18.8
	Low-Middle	19.6	19.4
	Middle	19.0	20.5
	High-Middle	19.6	20.5
	High	20.9	20.8

	Rural	27.1	26.7
<b>School Type</b>	Public	88.5	88.5
	Private/Catholic	11.5	11.5
<b>Gender</b>	Female	50.0	49.1
	Male	50.0	50.9

<sup>1</sup>National Center for Educational Statistics, United States Department of Education, 2015 Census Data

## **Norms Development**

The NNAT3 2017 updated norms were developed using *inferential norming* (Wilkins, Rolfhus, Weiss & Zhu, 2005; Zhu & Chen, 2011). The first three *moments* (mean, standard deviation, and skewness) of scaled scores were calculated for each year of age. The moments were plotted across age, and various polynomial regressions, ranging from linear to fifth degree polynomial, were fitted to the moment data. Selecting the best-fitting curve for each moment was based on

consistency with underlying theoretical expectations and the pattern of growth curves observed in the normative sample. The selected curves were used to derive estimated population moments by age. Then, those estimates were used to generate a theoretical distribution for each normative age group, yielding an age-based percentile for each scaled score. These percentiles were converted to standard scores on a normal (bell curve) distribution with a mean of 100, a standard deviation of 16, and a range of 40 to 160. The progression of standard scores within and across age groups was then examined, and minor irregularities were eliminated by smoothing. Appendix B presents the 2017 updated NAI equivalents of scaled scores in one-month intervals for ages 4 years 0 months to 9 years 11 months, and in three-month intervals from 10 years 0 months to 11 years 11 months.

The other derived scores—percentile ranks, stanines, and normal curve equivalents—have the same relationship to NAI scores as they did in the original NNAT3 norms. Therefore, Appendix C, which shows the conversion of NAI scores, is unchanged.

## COMPARISON OF NNAT3 2015 AND 2018 UPDATED LOWER LEVELS NORMS

Table 5.2 reports the means, standard deviations, and intercorrelations of NAI scores in the normative update sample, using both the 2015 norms and the 2018 updated norms. As expected, the NAIs based on the two sets of norms were almost perfectly correlated because the primary effect of the normative update was to shift NAI scores downward. At each level, mean NAI scores based on the updated norms were about four and a half points lower than those based on the original (2015) norms. Using the updated norms, 10.9% of the students in the 2018 normative update sample scored 120 or above, very close to the 10.6% expected in a normal distribution.

**Table 5.2. Comparison of NAI Scores from the 2015 and 2018 Updated Norms**

<b>Level</b>	<b>N</b>	<b>2015 Norms</b>		<b>2018 Norms Updated</b>		<b>Difference</b>	<b>r</b>
		<b>Mean</b>	<b>SD</b>	<b>Mean</b>	<b>SD</b>		
<b>A</b>	9,393	103.0	16.3	98.6	16.4	4.4	.999
<b>B</b>	11,090	106.0	17.2	101.5	16.9	4.5	.999
<b>C</b>	44,015	103.6	15.9	99.1	15.6	4.5	.999
<b>D</b>	13,956	106.2	16.0	101.8	16.0	4.4	.998
<b>All</b>	78,454	104.3	16.2	99.9	16.0	4.4	.999

*Note.* The average correlation coefficient across all levels was calculated using Fisher's Z transformation.

## Standard Error of Measurement

The standard error of measurement (SEM) indicates the precision of a score, that is, the amount by which it would be expected to vary across administrations (assuming no practice or fatigue effects). The change in the norm-sample standard deviation of NAI scores that resulted from the normative update affected the SEM of NAI scores. Table 5.3 presents the SEM of NAI scores at each test level, based on the updated norms and the IRT-based reliabilities reported in Table 4.1. Because those reliabilities were the same on both forms at each level and calculated with reference to the standard deviation of ability scores at each level in the overall norm sample, Table 5.3 provides a single SEM that is applicable to both forms at each level.

**Table 5.3. Standard Error of Measurement of 2018 NAI Scores, by Level**

Level	N	Mean	SD	Reliability	SEM of NAI
A	1,856	90.9	16.2	0.88	5.6
B	1,687	99.5	17.0	0.88	5.9
C	1,922	94.6	14.4	0.84	5.8
D (Grade 3)	1,103	96.1	13.0	0.80	5.8
D (Grade 4)	1,017	95.5	14.5	0.83	6.0

*Note.* Calculated using the IRT-based reliabilities reported in Table 4.1.

## RE-ANALYSIS OF VALIDITY STUDIES

In principle, the correlation of NNAT3 with other tests should have been affected little, if at all, by the normative update. The primary effect expected of the updated norms was a shift of all students' NAI scores, which would have little impact on the rank ordering of students' scores and, therefore, little effect on correlations with other variables. However, so that users could compare average NNAT3 (2017) NAI scores with average scores on other tests, the updated norms were used to re-analyze the NNAT3 correlation studies with NNAT2 and OLSAT 8 (reported in Chapter 4). Results are presented in Tables 5.4 and 5.5.

**Table 5.4. Correlations Between NNAT3 (2018 Updated) and NNAT2 NAI Scores**

Level	NNAT2 First						NNAT3 First						Mean
	NNAT2			NNAT3			NNAT2			NNAT3

		Total					.55	
<b>Mean<sup>b</sup></b>		Verbal					.42	
		Nonverbal					.57	

<sup>a</sup>Correlation adjusted for range restriction on NNAT3 (Cohen, Cohen, West, & Aiken, 2003)

<sup>b</sup>Using Fisher's z transformation

NNAT3 correlated slightly higher with NNAT2 when the updated norms were used (average of .79 versus .78). NNAT3 correlations with OLSAT 8 were unaffected, on average. In the NNAT3–NNAT2 study, the difference in mean NAI scores (averaged across administration sequences) was about 5 points at Level A, but near zero at Levels B and C. At Level D, where only one sequence was given, the difference of 3.1 points could reasonably be attributed to the practice effect, suggesting that NNAT3 and NNAT2 NAI scores were very similar at this level as well. In the NNAT3–OLSAT 8 study, where NNAT3 was always administered first, the effect of practice could not be removed statistically. At Levels A through C, NNAT3 scores were about 3 points lower than OLSAT 8 Total SAI scores, a difference that was consistent with a practice effect and with the Flynn effect. At Level D, NNAT3 scores were slightly higher than OLSAT 8 scores.

40–65	1	1	1

## **APPENDIX D: LIST OF SCHOOLS PARTICIPATING IN 2015 STANDARDIZATION**

**Alabama**

Christ the King School

**Arizona**

Aire Libre Elementary School  
Arrowhead Elementary School  
Beibei Amigos Language School  
Cactus View Elementary School  
Campo Bello Elementary School  
Desert Cove Elementary School  
Desert Mesa Elementary School  
Eagle Ridge Elementary School  
Echo Mountain Primary School  
Hidden Hills Elementary School  
Indian Bend Elementary School  
Larkspur Elementary School  
Palomino Primary School  
Ruth Fisher Elementary School  
Sunset Canyon School  
Tartesso Elementary School  
Whispering Wind Academy

**California**

Camellia Basic Elementary School

**Colorado**

Green Mountain Elementary School  
Teaching Tree Early Childhood Learning Center  
United Day Care Center

**Connecticut**

Central Christian Academy

**Florida**

Bethany Christian School  
Bradenton Christian School  
NCEF Early Childhood Development Center  
Union Baptist Educational Center

**Georgia**

Benton Elementary School  
Bleckley County Primary School  
Cloverleaf Elementary

**Iowa**

Dr. Walter Cunningham School for Excellence  
Highland Elementary School  
Kingsley Elementary School  
Lincoln Elementary School  
New Hartford Elementary School  
Orange Elementary School  
Willowwind School

**Idaho**

Aberdeen Elementary School  
Homedale Elementary School  
Melba Elementary School

**Illinois**

Glencoe School  
Glencoe Park District  
Northfield Community Nursery School  
Winnetka Public School Nursery

**Indiana**

Blackhawk Christian School  
Highland Park Elem School  
Sand Creek Elementary  
West Noble Primary School

**Kansas**

Genesis Christian School  
Holy Rosary Wea Catholic School

**Kentucky**

Audubon Elementary School  
North Hancock Elementary School  
Whitesville Elementary School

**Massachusetts**

Brookwood School  
Florence Sawyer School  
Franklin D. Roosevelt K–8 School  
Neighborhood House Charter School  
New Beginnings Academy  
Sarah Greenwood  
The Hathaway School  
Passos Avante Preschool  
West Memorial

**Maryland**

Seven Oaks Elementary

**Michigan**

Forest Park School  
Friends Preschool & Kindergarten

**Minnesota**

Stevenson Elementary

**Missouri**

Smithville Elementary

**Nebraska**

Brownell-Talbot Lower School

**New Hampshire**

St. Augustin Preschool and Kindergarten

**Ohio**

Babeck Early Childhood School  
Columbus Bilingual Academy  
Horizon Science Academy  
Liberty Bible Academy  
Rivertree Christian School  
Westside Academy

**Oklahoma**

Barnes Elementary

**Midwest City Elementary**

Miss Helen's Private School  
Parkview Elementary  
Ridgecrest Elementary  
Schwartz Elementary

**Oregon**

McKinley Elementary School

**Pennsylvania**

Learning Tree School  
Olney Elementary  
Samuel Pennypacker School  
Trinity Academy  
Wyoming Valley Montessori School

**Tennessee**

Vision Preparatory Charter School

**Texas**

Blair Elementary  
Blanton Elementary  
Carrollton Elementary  
Central Elementary  
Country Place Elementary  
Davis Elementary  
Faith Lutheran Day School  
Farmers Branch Elementary  
Freeman Elementary  
Furneaux Elementary  
Good Elementary  
Kent Elementary  
La Villita Elementary  
Landry Elementary  
Las Colinas Elementary  
Lujan-Chavez Elementary  
McCoy Elementary  
McKamy Elementary  
McLaughlin Strickland Elementary  
McWhorter Elementary

Rainbow Station Preschool  
Rainwater Elementary  
Resurrection Catholic School  
Riverchase Elementary  
Rosemeade Elementary  
Sheffield Elementary  
Stark Elementary  
Thompson Elementary

**Washington**

Holy Rosary School  
Sonshine Christian School and Daycare

**West Virginia**

St. Joseph Catholic School

**Wyoming**

Basic Beginnings  
Evanston Child Development Center
